A Course on DSGE Models with Financial Frictions Part 3: Asymmetric Information and Limited Commitment

Stelios Tsiaras

European University Institute

April 26, 2021

From Complete Markets to Financial Frictions

- To introduce financial frictions we need two deviations from the complete markets representative agent setting
    - Incomplete markets
    - Heterogeneous Agents

- A representative agent environment is in a sense an infinite agents setting where they can trade as much as necessary to eliminate idiosyncratic risk

- An example of market incompleteness:

- The Kiyotaki-Moore style collateral constraint $b_t \leq \theta k_t$

Financial Frictions: The BGG Model

- The two main streams of introducing financial frictions in DSGE models are
  - Asymmetric information
  - Limited commitment

- In this lecture we will go through one of the most seminal papers in the literature the Bernanke *et al.* (1999)

- it is a canonical NK model with a friction between the banks and the firms (called entrepreneurs)

- Eliminates $\mathbb{E}_t[\Lambda_{t,t+1}R_{t+1}] = \mathbb{E}_t[\Lambda_{t,t+1}R_{t+1}^K]$ of the RBC model and introduces a spread between the two discounted expected returns

Summary of the Model

- Main agents in the model: Households, entrepreneurs, retailers and a government

- Households work, consume and save in deposits

- Entrepreneurs are risk neutral. They purchase physical capital and produce goods with capital and labour

- Finance capital purchases with their net worth and bank credit

- Retailers are present to introduce nominal rigidities without complicating the entrepreneurs problem
  - Production side: NK framework with monopolistically competition and sticky prices

  - We will not go through that today

Entrepreneurs: Overview

- The entrepreneur j borrows loans B_t from the financial intermediary at time t to purchase capital K_t

- Loans together with her net worth $N_{E,t}$ finance the expenditure on new capital $Q_t K_t$.

- Entrepreneur's balance sheet therefore is:

$$B_t = Q_t K_t - N_{E,t} \tag{1}$$

where Q_t is the price of capital

Entrepreneurs: The Friction

- At every t the entrepreneur receives an idiosyncratic shock ω_t

- Results in return on capital: $\omega_t R_t^K$
    - ω_t is iid across all entrepreneurs

    - Drawn from a density $f(\omega_t)$ with mean $E(\omega_t)=1$

- ω_t^j is only observable by entrepreneur j

- Costly State Verification (CSV) Townsend (1979): Lenders to observe the state, need to pay a monitoring cost, a proportion μ of the gross return $\mu R_{t+1}^K Q_t K_t$

Entrepreneurs: No Aggregate Risk

- We start with the case of no aggregate risk
  - R_{t+1}^K is known in advance and only uncertainty is idiosyncratic to the firm
  - The optimal contract is a risky debt contract (see Appendix A of Bernanke *et al.* (1999) for more)

- Entrepreneurs choose B_t and $Q_t K_t$ given R_t^K

- The optimal contract can be characterized by a gross non-default loan rate Z_t and a threshold value for the idiosyncratic shock $\bar{\omega}_t$

$$\bar{\omega}_{t+1} = \frac{Z_t B_t}{R_{t+1}^K Q_t k_t} \tag{2}$$

Entrepreneurs: Optimal Contract

- Entrepreneurs who receive a $\omega_t \geq \bar{\omega}_t$
  - Repay the intermediary $Z_t B_t$

  - Keep the difference $\bar{\omega}_{t+1} R^K_{t+1} Q_t k_t - Z_t B_t$

- Entrepreneurs who receive a $\omega_t < \bar{\omega}_t$
  - Default and get nothing

  - Intermediary pays the monitoring costs and gets what it finds: $(1 - \mu) R^K_{t+1} Q_t K_t$

Entrepreneurs: Optimal Contract

- Under the optimal contract the lender should receive an expected return equal to its opportunity cost of funds

- Here, our bank's balance sheet is $B_t = D_t$ where D_t (deposits by households) is remunerated at the riskless rate R_t

- The loan contract must satisfy the bank's incentive compatibility constraint at time t

$$\underbrace{(1-\mu)R_{t+1}^K Q_t K_t \int_0^{\bar{\omega}_{t+1}} \omega f(\omega) d\omega}_{\text{Default}} + \overbrace{(1-p(\bar{\omega}_{t+1}))Z_t B_t}^{\text{No default}}$$

$$= R_t B_t$$

Entrepreneurs: Optimal Contract

- Using the Z_t from $\bar{\omega}_{t+1} = \frac{Z_t B_t}{R_{t+1}^K Q_t k_t}$, the constraint becomes

$$R_{t+1}^K Q_t K_t \left((1 - \mu) \int_0^{\bar{\omega}_{t+1}} \omega f(\omega) d\omega + \bar{\omega}_{t+1}(1 - p(\bar{\omega}_{t+1})) \right) \geq R_{t+1} B_t \qquad (3)$$

- To simplify notation a bit let $\Gamma(\bar{\omega}_{t+1})$ to be the fraction of net capital received by the lender (the bank)

- $\mu G(\bar{\omega}_{t+1})$ to be monitoring costs:

$$\Gamma(\bar{\omega}_{t+1}) \equiv \int_0^{\bar{\omega}_{t+1}} \omega f(\omega) d\omega + \bar{\omega}_{t+1}(1 - p(\bar{\omega}_{t+1})) \qquad (4)$$

$$G(\bar{\omega}_{t+1}) \equiv \int_0^{\bar{\omega}_{t+1}} \psi f(\omega) d\omega \qquad (5)$$

Entrepreneurs: Introducing Aggregate Risk

- So far we were abstracting from aggregate risk

- Now price and return of capital are given but uncertain

- $\bar{\omega}_{t+1}$ will now generally depend on the ex-post realization of R_{t+1}^K

- Entrepreneur is willing to offer a return that is free of any aggregate risk
  - Conditional on the return R_{t+1}^K the borrower offers state contingent non-default payment guaranteeing an expected return equal to the riskless rate

  - IC now implies a set of contracts for each realization of R_{t+1}^K

Entrepreneurs: Net Worth and Optimal Choice of Capital

- The entrepreneur's payoff is

$$\mathbb{E}_t \left[R_{t+1}^K Q_t K_t \int_{\bar{\omega}_{t+1}}^{\infty} \omega f(\omega) d\omega - (1 - p(\bar{\omega}_{t+1})) Z_t B_t \right] =$$

$$\mathbb{E}_t \left[\left(1 - \Gamma(\bar{\psi}_{t+1}) \right) R_{t+1}^K Q_t K_t \right] \tag{6}$$

- She maximizes (6) given the net worth $N_{E,t}$, subject to the IC constraint (3) which, using (1), (4) and (5), can be rewritten as

$$\mathbb{E}_t \left[R_{t+1}^K Q_t K_t \left[\Gamma(\bar{\omega}_{t+1}) - \mu G(\bar{\omega}_{t+1}) \right] \geq R_{t+1}(Q_t K_t - N_{E,t}) \right]$$

Entrepreneurs: Solution

- Let λ_t be the Lagrange multiplier associated with the IC constraint. Then the first order conditions are

$$K_t \quad : \quad \mathbb{E}_t\left[(1 - \Gamma(\bar{\omega}_{t+1})R^K_{t+1} + \lambda_t\left[(\Gamma(\bar{\omega}_{t+1}) - \mu G(\bar{\omega}_{t+1}))R^K_{t+1} - R_{t+1}\right]\right] = 0$$

$$\bar{\omega}_{t+1} \quad : \quad \mathbb{E}_t\left[\Gamma'(\bar{\omega}_{t+1}) + \lambda_t(\Gamma'(\bar{\omega}_{t+1}) - \mu G'(\bar{\omega}_{t+1}))\right] = 0$$

  plus the binding IC condition if $\lambda_t > 0$ with $\lambda_t = 0$ if it does not bind.

- Combining these two conditions, we arrive at

$$\mathbb{E}_t[R^K_{t+1}] = \mathbb{E}_t[\rho(\bar{\omega}_{t+1})R_{t+1}]$$

  where the *premium on external finance*, $\rho(\bar{\omega}_{t+1})$ is given by

$$\rho(\bar{\omega}_{t+1}) = \frac{\Gamma'(\bar{\omega}_{t+1})}{[(\Gamma(\bar{\omega}_{t+1}) - \mu G(\bar{\omega}_{t+1}))\Gamma'(\bar{\omega}_{t+1}) + (1 - \Gamma(\bar{\omega}_{t+1}))(\Gamma'(\bar{\omega}_{t+1}) - \mu G'(\bar{\omega}_{t+1}))]}$$

External Finance Premium

- The external finance premium equation replaces the no arbitrage condition between R^K and R in NK and RBC models

- External finance is given by the safe rate, scaled up by a premium term

- Note that in the limiting case of $\bar{\omega}_{t+1} = 0$ and the probability of default tend to zero and $\mu = 0$, $\Gamma \to 0$ and the risk premium $\rho(\bar{\omega}_{t+1}) \to 1$ going back to the frictionless RBC

Aggregation

- Entrepreneurs exit with a fixed probability $(1 - \sigma_E)$

- New entrants get a start-up transfer equal to ξ_E of the old entrepreneurs wealth

- Aggregate net worth is

$$N_{E,t} = (\sigma_E + \xi_E)(1 - \Gamma(\bar{\omega}_t))R_t^K Q_{t-1} K_{t-1}$$

- Entrepreneur who exit (die) consume

$$C_{E,t} = (1 - \sigma_E)(1 - \xi_E)(1 - \Gamma(\bar{\omega}_t))R_t^K Q_{t-1} K_{t-1}$$

- The economy's resource constraint then is

$$Y_t = C_t + C_{E,t} + G_t + I_t + \mu G(\bar{\psi}_t)R_t^K Q_{t-1} K_{t-1}$$

General Equilibrium

- Households work, consume, save and pay taxes
    - Their budget constraint therefore is:

$$C_t + D_t + T_t = W_t L_t + R_t D_{t-1}$$

- Banks are very simple, get deposits D_t from the households and provide loans B_t to the entrepreneurs at a rate Z_t

$$B_t = D_t$$

- Government has a balanced budget: $G_t = T_t$

- Production side in the BGG is NK

- Here we will just follow the RBC model structure

General Equilibrium

- Capital accumulation with investment adjustment costs carried out by **Capital Producers**

$$
\begin{aligned}
K_t &= (1-\delta)K_{t-1} + (1-S(X_t))I_t \\
X_t &\equiv \frac{I_t}{I_{t-1}} \\
S(X_t) &= \phi_X(X_t - 1)^2 \\
S'(X_t) &= 2\phi_X(X_t - 1) \\
Q_t(1 - S(X_t) - X_t S'(X_t)) &+ \mathbb{E}_t\left[\Lambda_{t,t+1} Q_{t+1} S'(X_{t+1}) X_{t+1}^2\right] = 1
\end{aligned}
$$

- $S(X_t)$ are investment adjustment costs equal to zero in a balance growth steady state

Summary of Equilibrium

$$Y_t = C_t + C_{E,t} + G_t + I_t + \mu G(\bar{\psi}_t)) R_t^K Q_{t-1} K_{t-1}$$
$$C_{E,t} = (1 - \sigma_E)(1 - \xi_E)(1 - \Gamma(\bar{\psi}_t)) R_t^K Q_{t-1} K_{t-1}$$

$$B_t = Q_t K_t - N_{E,t}$$
$$\bar{\omega}_t = \frac{Z_{t-1} B_{t-1}}{R_t^K Q_{t-1} K_{t-1}}$$
$$R_t^K = \frac{r_t^K + (1 - \delta) Q_t}{Q_{t-1}}$$
$$r_t^K = \frac{(1 - \alpha) Y_t}{K_{t-1}}$$

Steady State Equilibrium

- The zero growth steady state is given by

$$
\begin{aligned}
R_k &= \rho(\bar{\psi})R \\
N_E &= (\sigma_E + \xi_E)(1 - \Gamma(\bar{\psi}))R_kQK \\
R_kQK\left[\Gamma(\bar{\psi}) - \mu G(\bar{\psi})\right] &= R(QK - N_E) \text{ or} \\
R_k[\Gamma(\bar{\psi}) - \mu G(\bar{\psi})] &= R(\phi - 1)
\end{aligned}
$$

- where $\phi \equiv \frac{QK}{N_E}$ and

$$
\rho(\bar{\psi}) = \frac{\Gamma'(\bar{\psi})}{\left[(\Gamma(\bar{\psi}) - \mu G(\bar{\psi}))\Gamma'(\bar{\psi}) + (1 - \Gamma(\bar{\psi}))(\Gamma'(\bar{\psi}) - \mu G'(\bar{\psi}))\right]}
$$

Steady State Equilibrium

- with a resource constraint

$$Y = C + C_E + G + I + \mu G(\bar{\psi}) R_k Q K$$
$$C_E = (1 - \sigma_E)(1 - \xi_E)(1 - \Gamma(\bar{\psi})) R_k Q K$$

- and post-recursive equations

$$L = QK - N_E$$
$$R_l = \frac{\bar{\psi} R_k Q K}{L}$$
$$R_k = \frac{Z + (1 - \delta)Q}{Q}$$
$$Z = \frac{(1 - \alpha)Y}{K}$$

The Density Function

- BGG choose a log-normal distribution.

- Thus $\omega_t = e^{x_t}$ where $x_t \sim N(-\frac{1}{2}\sigma_\omega^2, \sigma_\omega^2)$

- This guarantees that $\mathbb{E}[\omega_t] = 1$

Calibration

- Production parameters, same as in the simple RBC

- For NK extension see code in GitHub

- Additional financial parameters to calibrate are σ_ω, σ_E, and μ.

- These three parameters are calibrated to hit four targets:
  (1) a default probability $p(\bar{\psi}) = 0.05$,

  (2) $\rho(\bar{\psi}) = 1.0025$ corresponding to a credit spread of 100 basis points as in GK,

  (3) an entrepreneur leverage $\frac{QK}{N_E} = 2$ as in BGG
Calibration

- With these values the calibrated parameters are:

Parameter	Calibrated Value
σ_ψ	0.3135
σ_E	0.9764
μ	0.0284

Impulse Responses: Productivity Shock (positive)
Impulse Responses: Risk Shock (negative)

Christiano, Motto and Rostagno (2014) extension

- Built on the Bernanke *et al.* (1999)

- Under a NK framework

- Lots of additional frictions and shocks (capacity utilization rate, taxes, long-term bonds...)

- *Estimated* for the US economy

The Risk Shock

- They refer to as risk the time period t cross-sectional standard deviation of $\log(\omega)$

- Risk is high in periods when $\sigma_{\omega,t}$ is high, and there is substantial dispersion in the outcomes across entrepreneurs

- Model estimation assigns a large role to $\sigma_{\omega,t}$

- Disturbances in $\sigma_{\omega,t}$ trigger responses in the model that resemble actual business cycles

- They find that fluctuations in $\sigma_{\omega,t}$ account for 60 percent of the fluctuations in the growth rate of aggregate US output since the mid-1980s

The Risk Shock

- Essentially from being a parameter $\sigma_{\omega,t}$ now follows an AR(1) process
  `log(sigma`$_o$`mega/sigma`$_o$`mega`$_s$`s) =`
  $rhosigma * log(sigma_omega(-1)/sigma_omega_s s) + e_R S;$
  $\log(\omega)$

- Risk is high in periods when $\sigma_{\omega,t}$ is high, and there is substantial dispersion in the outcomes across entrepreneurs

- Model estimation assigns a large role to $\sigma_{\omega,t}$

- Disturbances in $\sigma_{\omega,t}$ trigger responses in the model that resemble actual business cycles

- They find that fluctuations in $\sigma_{\omega,t}$ account for 60 percent of the fluctuations in the growth rate of aggregate US output since the mid-1980s
